seen by the GW  
detectors

The (disputed)  
existence of IMBHs

Modeling BBH  
coalescence

Event rates of IMBH  
binaries

Summary and  
Conclusions

# Different detectors for different sources

- ▶ **Current ground-based GW astronomy:** neutron-star binaries and solar-mass BBHs. Scarce sources (for now) – around-threshold events
- ▶ **Space-based projects:** SMBHs, EMRIs, galactic binaries. Abundance of sources – huge SNRs
- ▶ **ET:** IMBHs? Expected event rates? Foreground noise?

Coalescences of IMBH binaries as sources for the future ET detector

IMBH binaries as seen by the GW detectors

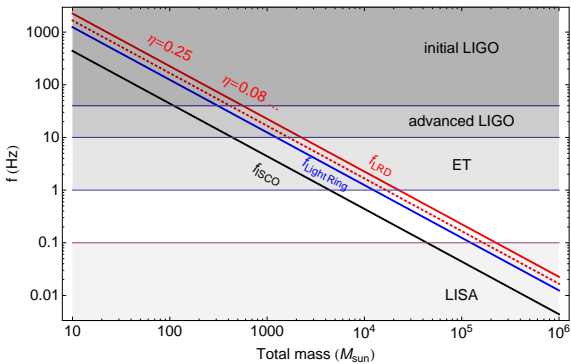

The (disputed) existence of IMBHs

Modeling BBH coalescence

Event rates of IMBH binaries

Summary and Conclusions

# ET opens a window in the intermediate-mass region

- ▶ As total mass of the system increases, BBHs merge at lower frequencies
- ▶ Shown are the ISCO ( $r = 6M$ ), Light ring ( $r = 3M$ ) and Lorentzian ringdown (after merger) frequencies of equal-mass ( $\eta = 0.25$ ) and 1:10 ( $\eta = 0.08$ ) binary systems  $\left[ \eta \equiv \frac{m_1 m_2}{(m_1 + m_2)^2} \right]$
- ▶ While LIGO's efforts are targeted towards stellar-mass binaries, LISA will see mergers of supermassive BBHs (and also IMBHs' *inspirals*)
- ▶ **ET will open a window in the intermediate-mass region  $10^2 - 10^4 M_\odot$**
- ▶ IMRIs and IMBH-IMBH binaries. In this talk: IMBHs!

Coalescences of IMBH binaries as sources for the future ET detector

Modeling BBH  
coalescence

Event rates of IMBH  
binaries

Summary and  
Conclusions

# The ET and LISA

IMBHBs with masses of hundreds of  $M_\odot$  could be seen by *both* LISA and the ET

The long inspiral seen in the LISA band will allow for precise estimation of the parameters of the binary

The merger of the IMBHB within the ET band would produce high-SNR events

Coalescences of

detectors

The (disputed)  
existence of IMBHs

Modeling BBH  
coalescence

Event rates of IMBH  
binaries

Summary and  
Conclusions

# But do IMBHs exist?

There is indirect evidence but also uncertainties...

- If yes, formed after collapse of a Very Massive Star
- Double-cluster channel: in systems of two grav.-bound clusters, IMBHs sink down to the centers
- Single-cluster channel: in clusters with a fraction of primordial binaries  $> 10\%$  two IMBH might form
- Observed ultraluminous X-ray sources could be explained by accretion onto IMBHs

BUT there are also works suggesting that VMSs will not form in this way  
GW astronomy might as well beat traditional astronomy in this case!

# Theoretical models of BBH coalescence

GW searches of known signals require **templates**

BBH coalescence: 2-body problem in GR in vacuum:  $R_{\mu\nu} = 0$

Evolution of 2 distant BHs inspiralling around each other in a quasi-circular orbit  
→ for the moment we will ignore the role of eccentricity!

Summary and  
Conclusions

# Phenomenological PN-NR model in the frequency domain

▶  $\tilde{h}(f) = A(f)e^{i\phi(f)}$

For comparable-mass systems: radiation mainly in the  $\ell = 2, m = 2$  mode

- ▶ Amplitude: PN with corrections up to 3PN + NR waveforms at null infinity  
new AEI Llama code + Cauchy characteristic extraction (Reisswig *et al.* 2009)
- ▶ Phase: PN up to 3.5PN + NR (but not needed for SNR calculations)
- ▶ Convenience of using a frequency domain model (SNR, horizon distance: integrals of FD quantities)
- ▶ Parametrized as function of  $(M, \eta, \chi)$  for spin-aligned systems  
→ [Santamaria \*et al.\* to be submitted \(2010\)](#)

Summary and  
Conclusions

## Yes, but how many of those IMBHs are out there?

- ▶ Assuming that formation of IMBHs in stellar cluster is possible
- ▶ Following Fregeau *et al.* (2006) and Miller (2002)
- ▶ The integral to compute is

$$R = \frac{dN_{\text{event}}}{dt_0} = \int_0^{z_{\text{max}}} \frac{d^2 M_{\text{SF}}}{dV_c dt_e} g_{\text{cl}} g \frac{dt_e}{dt_0} \frac{dV_c}{dz} \int_{M_{\text{cl},\text{min}}}^{M_{\text{cl},\text{max}}} \frac{d^2 N_{\text{cl}}}{dM_{\text{SF},\text{cl}} dM_{\text{cl}}} dM_{\text{cl}} dz$$

- ▶  $R$  is the event rate observed at  $z = 0$
- ▶  $dt_e/dt_0 = (1+z)^{-1}$  and  $dV_c/dz$  rate of change of comoving volume (depends on cosmological model)
- ▶  $d^2 M_{\text{SF}}/dV_c dt_e$  star formation rate in mass per unit of comoving volume per unit of local time (peaks at  $1 < z < 2$  then decreases and stays  $\sim$  constant)
- ▶  $d^2 N_{\text{cl}}/dM_{\text{SF},\text{cl}} dM_{\text{cl}}$  distribution function of clusters over individual cluster mass  $M_{\text{cl}}$  and total star-forming mass in clusters  $M_{\text{SF},\text{cl}}$  ( $\propto 1/M_{\text{cl}}^2$ )
- ▶  $g$  fraction of clusters where IMBH are formed (???  $g \sim 0.1$ )
- ▶  $g_{\text{cl}}$  fraction of star-forming mass that goes into star clusters more massive than  $10^{3.5} M_{\odot}$  (???  $g_{\text{cl}} \sim 0.1$ )
- ▶  $z_{\text{max}}$  Maximum redshift to which ET is capable of seeing an IMBH coalescence (can be calculated given expected GW signal and PSD)

binaries

Summary and  
Conclusions

# How far is ET capable of seeing?

**Horizon distance:** distance at which a detector can detect a waveform from an optimally oriented, overhead source at an SNR threshold of 8.

[ ..... ET      - - - adv LIGO ]

$z_{max}(ET) \sim 20 \Rightarrow$  could even probe seed BHs

\* for the  $\eta = 0.25$  non-spinning waveform shown before. Orbital hang-up configurations with large spins might yield horizon distances  $\sim 50\%$  larger!

Summary and  
Conclusions

## And what are the final numbers?

We follow Fregeau *et al* (2006) but consider the *two* possible channels for IMBH formation [Amaro-Seoane & Freitag (2006)]

$$\Gamma^{\text{doub}} = P_{\text{merg}} P_{\text{ra}} \Gamma^{\text{sing}}$$

( $P_{\text{ra}}$  probability that a cluster gets into the runaway phase)

( $P_{\text{merg}}$  probability for two clusters to collide)

## And what are the final numbers?

We follow Fregeau *et al* (2006) but consider the *two* possible channels for IMBH formation [Amaro-Seoane & Freitag (2006)]

$$\Gamma^{\text{doub}} = P_{\text{merg}} P_{\text{ra}} \Gamma^{\text{sing}}$$

( $P_{\text{ra}}$  probability that a cluster gets into the runaway phase)

( $P_{\text{merg}}$  probability for two clusters to collide)

Fregeau *et al* (2006) estimate  $d_L = 2 \text{Gpc} (z \approx 0.4)$  for advanced LIGO, which yields (pessimistic and optimistic values depending on the estimations for  $g$  and  $g_{cl}$ )

For Advanced LIGO:

$$\Gamma_{\text{Adv. LIGO}}^{\text{total}} \in [(0) 11, 300] \text{ yr}^{-1}.$$

For the ET:

$$\Gamma_{\text{ET}}^{\text{total}} \in [(0) 4000, 6 \cdot 10^4] \text{ yr}^{-1}$$

These numbers are obviously encouraging enough to expect that IMBHs will be potentially **important sources for advanced LIGO/Virgo and the ET**

But NOTE that the rates are **greatly underestimated for ET**, which will see up to  $z \sim 20$ . Work is in progress to recalculate the expected event rates for the ET [Amaro-Seoane & Santamaria (2010)]

binaries

Summary and  
Conclusions

## Conclusions

- ▶ IMBH detection would be of extreme importance for theoretical astrophysics. This rather speculative scenario could be solved within the next decade (with advLIGO) and/or later with the ET
- ▶ Single- and double-cluster channel: possible formation channels for IMBH binaries in stellar clusters
- ▶ LISA will only see the inspiral stage, for IMBH binaries merge outside its band
- ▶ Detection and characterization of compact binary coalescence rely on theoretical source models. For IMBHs, comparable-mass scenarios expected (PN+NR appropriate)
- ▶ Large SNR events will be associated to the merger and ringdown of IMBH systems within the sensitivity band of the ET. Computation of  $z_{max}$  indicates that the ET will see to very high distances - this translates into large expected event rates!
- ▶ Prospects for detection and characterization of IMBH binaries with the ET look very encouraging
